- Summary

# Motivation

Met Office NWP model contained  
freely evolving snow amounts

Not enough  
Too much  
variability  
Early  
snowmelt

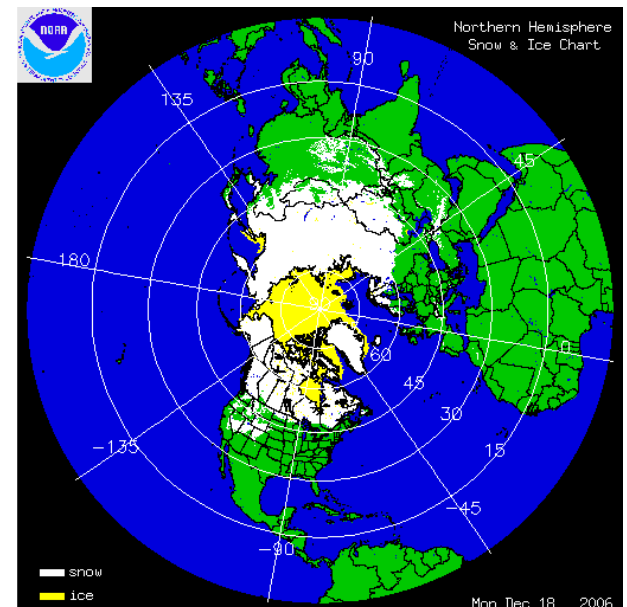

- Improve snow analysis
- Improve forecasts of screen level variables
- Enable use of more satellite soundings over land – potential large impacts for atmospheric forecasts

# Satellite data

## NESDIS Interactive Multisensor Snow and Ice Mapping System (IMS)

- GEO, LEO (GOES, Meteosat, MTSAT, AVHRR, MODIS, SSM/I, AMSU)
  - Derived products (e.g. USAF Snow and Ice Analysis Product)
  - In situ data
  - Analyst
- 
- Daily, 4km resolution, NH
  - Polar stereographic 6144 X 6144
  - Snow cover (0 or 100), ice (0 or 1)
  - Received in Met Office since Nov 2006

# The snow analysis scheme

## Phase 1

- IMS snow cover is binary but model variable is snow amount, or areal density, ( $\text{kgm}^{-2}$ )
- Average IMS snow cover onto UM grid to create fractional cover
- Use short f/c from previous cycle as background
- Compare presence of snow in fractional cover and background and update the model where they disagree
- To add snow, relate fractional cover to areal density using:

$S$  = snow areal density  
 $D$  = masking depth of vegetation ( $0.2\text{m}^2\text{kg}^{-1}$ )  
 $f_c$  = fractional snow cover

$$S = ( - \log_e ( 1 - f_c ) ) / D$$

up to max of  
 $10.0 \text{ kgm}^{-2}$

Used successfully by Romonov et al. (2003)

- Carried out at 0600 UTC daily
- Implemented operationally in November 2008

# The snow analysis scheme

## Phase 1

### Observations

Frac cover = 0

Frac cover > 0

### Background

UM snow > 0

UM snow = 0

### Analysis

Analysed snow = 0

Analysed snow = UM snow

# Upgrade to the snow analysis

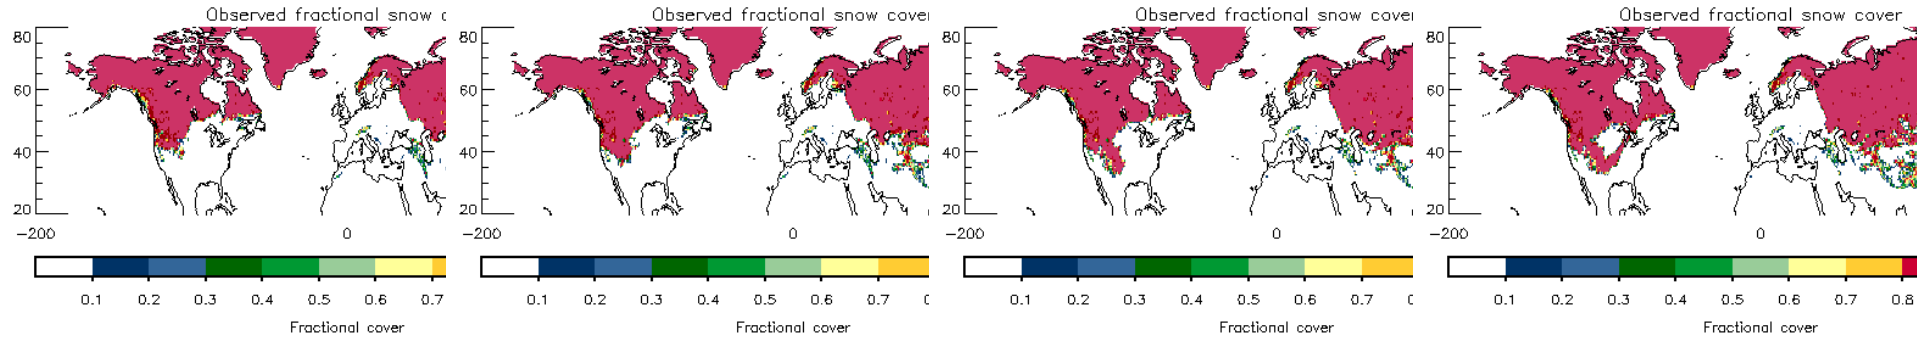

## Phase 2

Two improvements made to basic snow analysis:

1. Correct a bug that prevented snow being added to all relevant model points
2. Mitigate effects of time delay in IMS data
  - IMS snow product comprises data up to 36 hours old
  - Genuine snowfall events may be removed by the snow analysis as the IMS data has not yet recorded the snowfall.
  - Use previous day's background snow as additional constraint in cases of snow removal. Where the model forecasts a snowfall event well, IMS data may compare better with the previous day's background than the current one, in which case we can assume the model evolution is correct and make no change in the analysis.

# The snow analysis scheme

## Phase 2

Observations

Background

Analysis

Frac cover = 0

$(\text{UM snow})^{\text{day}-1} > 0$

Analysed snow = 0

$(\text{UM snow})^{\text{day}-1} = 0$

Analysed snow =  
UM snow

Frac cover > 0

UM snow > 0

Analysed snow =  
UM snow

UM snow = 0

# Assimilation experiments

## Phase 1: Implementing the snow analysis

- NH winter season, 1 month, Dec 2006
- NH spring season, 3 months, March-May 2007
- Control contains no snow analysis

Neutral  
impact on f/c  
RMSE scores

## Phase 2: Upgrading the snow analysis

- NH winter season, 1 month, Dec/Jan 2009/10
- NH spring season, 1 month, April 2009
- Control contains basic (phase 1) snow analysis

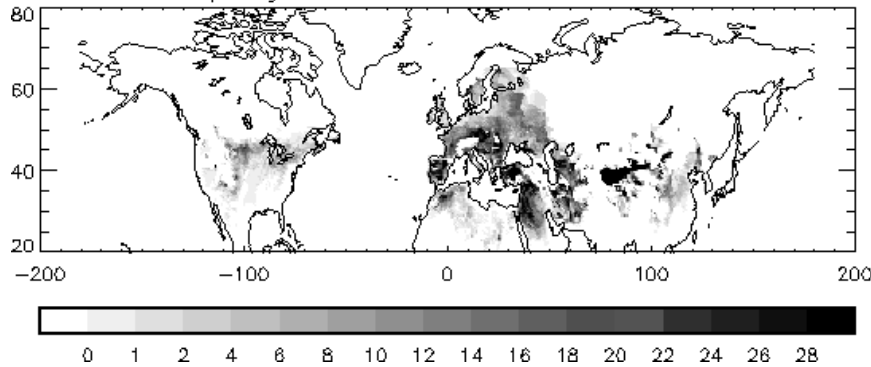

Neutral  
impact on f/c  
RMSE scores  
(-0.2% winter)

# Behaviour of the snow analysis

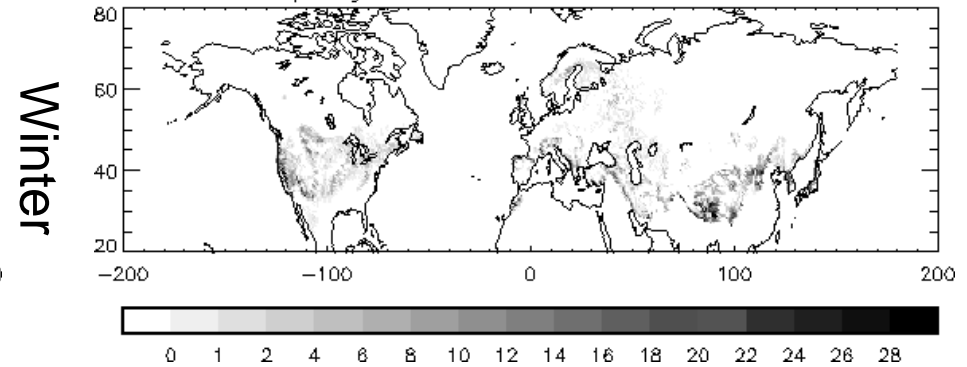

## Snow removed

Frequency of snow removals in December 2006

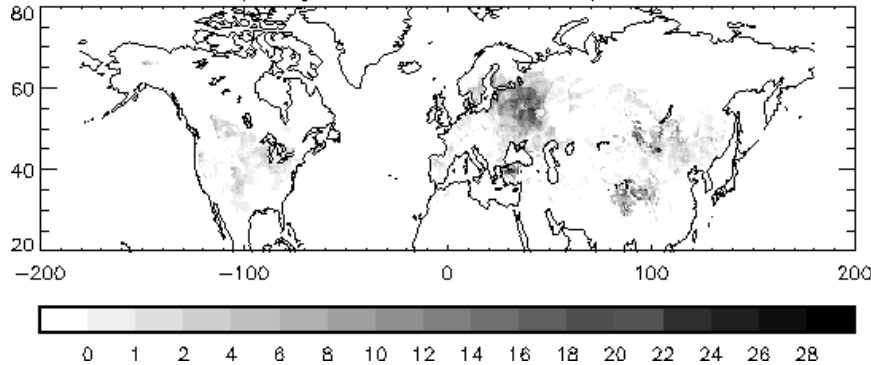

## Snow added

NATIONAL SNOW 2006- ANALYSIS 2007

# Presence of snow verified against SYNOP obs

## Snow analysis vs no snow analysis

## Upgraded snow analysis vs basic snow analysis

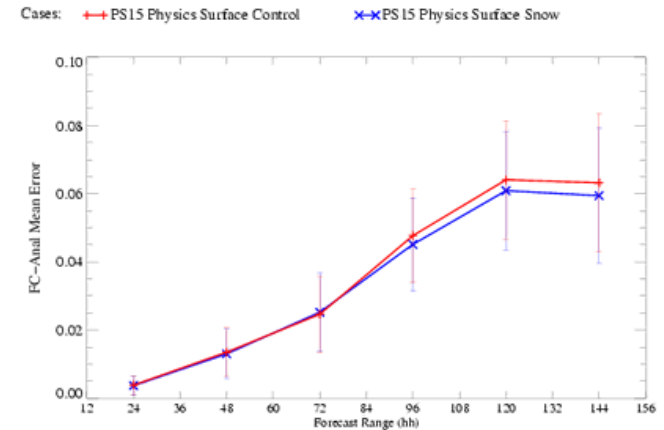

# Surface field verification

- Most changes small, especially for spring trial
- Surface or low level T generally improved
- Winter trial surface RH improved for Europe (mainly snow removal) and above surface improved for N America (mainly snow addition)
- Most consistent improvements in winter trial for Europe
- Small improvement in snow amount forecasts in winter trial for Europe
- Where snow is mainly added results are less positive

Snow depth (water equivalent): Analysis  
Europe (CBS area 70N–25N, 10W–28E)  
Equalized and Meaned from 27/11/2006 12Z to 31/12/2006 12Z

68% error bars calculated using  $S/(n-1)^{1/2}$

# Summary

- The Northern Hemisphere snow analysis has been operational in the Met Office's global NWP model since November 2008.
- There is clear evidence that the snow analysis improves the analysed snow field, in terms of presence/non-presence of snow
- There is some evidence of improvements in surface/low level T and RH, especially where snow is predominantly removed by the analysis.
- Little of the information introduced by the analysis is retained in subsequent forecasts, especially where snow has been added.
- An upgrade to the snow analysis, to mitigate the effects of time delays in the IMS data, is due to be implemented operationally in July.
- A new multilayer snow physics scheme will soon be implemented, which may help with snow retention
